July 2000

We appreciate the comments received from the participants at the Conference on Immigration with an International Perspective, Vancouver, January 1999, and the Applications Workshop, Department of Economics, University of Chicago, May 1999. This paper was written, in part, while Paul Miller was Visiting Professor, Department of Economics, University of Illinois at Chicago and while Barry Chiswick was John M. Olin Visiting Professor, Graduate School of Business, University of Chicago. Partial financial support for this project was provided by the Canadian Embassy, Washington, D.C., the George J. Stigler Center for the Study of the Economy and the State, University of Chicago, and the Vancouver Centre of Excellence: Research on Immigration and Integration in the Metropolis (RIIM). We thank Sydney Preston of RIIM for the final preparation of the manuscript.

**Abstract:** This paper analyzes the effects of language practice on earnings among adult male immigrants in Canada using the 1991 Census. Earnings are shown to increase with schooling, pre-immigration experience and duration in Canada, as well as with proficiency in the official languages (English and French). Using selectivity correction techniques, it is shown that there is a complementarity between language skills and both schooling and pre-immigration experience. That is, greater proficiency in the official languages enhances the effects on earnings of schooling and pre-immigration labor market experience. Language proficiency and post-migration experience appear to be substitutes, that is, those with greater proficiency have a smaller effect of time in Canada on earnings.

**JEL Classification:** I21 J31, J61

**Key Words:** education analysis, immigrant earnings, language skills, wage level, wage structure

## **I. Introduction**

Language skills are a form of human capital. As with other forms of human capital, language skills are created at a sacrifice of time and other resources, are embodied in the person and are productive. Previous research has shown for several immigrant-receiving countries that greater proficiency in the destination language enhances labor market earnings and that this investment provides a high rate of return (see, for example, Chiswick and Miller 1995). Destination language proficiency is presumably also productive in consumption activities.

The purpose of this paper is to extend the analysis of destination language skills among immigrants. It does this in two ways. First, it uses data from the 1991 Census of Canada to estimate the effect of language usage on earnings among immigrants in Canada. Previous studies for Canada relied primarily on the 1981 Census. Second, it extends the theoretical work by hypothesizing and then testing for whether destination language skills appear to be complements or substitutes in generating earnings with respect to other kinds of human capital, namely schooling and pre- and post-migration labor market experience. The analysis of earnings uses the now standard human capital earnings function adjusted to account for immigrant assimilation. The earnings function is estimated overall and using selectivity correction techniques separately by language use categories.

Section II outlines the model of the relation between destination language skills and other forms of human capital. Section III describes the data used in the analysis, the 1991 Census of Canada. Section IV presents the human capital earnings function that forms the basis of the empirical analysis and reports the findings of the analysis. Section V is the summary and conclusion.

## **II. The Model**

This study is concerned with the impact on earnings of the destination language proficiency of immigrants. Greater proficiency in the destination language can enhance earnings by enabling the

immigrants to find a better labor market match between their skills and the requirements of employers. Language proficiency can also have a direct impact on productivity through more efficient communication with supervisors, subordinates, peers, suppliers and customers. This greater efficiency in communication raises the productivity of labor.<sup>1</sup> Hence, earnings among immigrants are expected to be a rising function of the immigrant's proficiency in the destination language.

Destination language proficiency can have indirect impacts on labor market earnings through the effect on the productivity of other forms of human capital. For example, greater destination language proficiency may increase the returns from schooling and labor market experience. Schooling and pre-immigration labor market experience may be of little, if any, value to an immigrant with no knowledge of the destination language. In spite of a high level of schooling and job training, this person may be little different from an unskilled worker as far as the destination labor market is concerned. As this immigrant's destination language skills improve, the productivity of the schooling and pre-immigration experience in the destination labor market increases. Hence, it would be hypothesized that destination language skills have a complementary relationship in the labor market with respect to schooling and pre-immigration labor market experience.

There are various forms of destination-specific human capital, only one of which is destination language skills. Those making greater investments in destination language skills may also make greater (or lesser) investments in other forms of destination-specific human capital. These other forms of human capital are not measured directly but are reflected in the empirical analysis by the variable for duration of residence or length of stay in the destination. If there is a lesser intensity of investment in post-migration human capital other than language skills, the effect of duration on earnings is lowered (flattened) for two reasons. One is that foregone earnings are lower if there is less investment, and this mitigates the reduction in earnings in the investment period. The other is that there is a smaller increase in earnings from the post-migration investments. Then, if language proficiency and other forms of post-migration investments are

---

<sup>1</sup> The Biblical study of the Tower of Babel is relevant here (Genesis, Chapter 11). To thwart the efforts of people to work together to build a tower that would reach Heaven, God inflicted on the populous a multitude of languages. As a result of the increased costs of communication, as the story goes, the Tower was never completed.

substitute forms of investment, those with greater destination language proficiency will have a smaller increase in earnings with duration, holding language skills constant. On the other hand, if these investments are complementary, that is, if those who invest more in language skills also invest more in other forms of post-migration human capital, those with greater destination language proficiency will have a steeper rise in earnings with duration, other things being the same.

For a fixed level of post-migration investment, greater investments in language skills imply less investment in other forms of human capital. Yet those with a lower discount rate or a higher level of ability may invest more in all kinds of post-migration human capital. Moreover, if there is complementarity in the labor market between language and other post-migration investments immigrants who invest more in one form may invest more in both forms of human capital.<sup>2</sup>

As a result, it is hypothesized that among immigrants greater proficiency in the destination language enhances earnings and enhances the partial effect on earnings of schooling and pre-immigration labor market experience. The effect of greater investments in destination language skills on the partial effect of post-immigration experience is, however, ambiguous. It depends on whether the “expansion effect” (greater investment in all types of post-migration human capital) exceeds the “substitution effect” (substitution among sub-types for a given amount of post-migration investment).

### **III. Data**

This study uses the data from the 1991 Census of Canada, Public Use Microdata File (Individuals), 3 percent sample of the population. The Microdata file released from the Census contains information on knowledge of the official languages (English and French), knowledge of unofficial languages, the language usually used at home, and mother tongue.<sup>3</sup> The information on knowledge of the official languages and home language is used to construct the language proficiency explanatory variables that are the focus of the analysis. Information on mother tongue is

---

<sup>2</sup> This is analogous to the observation that those who invest in more schooling also appear to make greater investments in on-the-job training.

<sup>3</sup> For an analysis of these language questions and recommendations for improvements, see Chiswick and Miller (1998).

used to construct several exogenous variables that serve as identifying instruments in some models (see Appendix A).

The Census information on earnings, educational attainment, labor market experience, duration of residence and place of residence is quite standard. The description of these variables is contained in Appendix A. Appendix Table B-1 provides the means and standard deviations of the dependent and explanatory variables.

Table 1 reports data on the distribution of adult male immigrants across the three language groups. These data are for the sample of foreign-born males from non-English-speaking countries between the ages of 25 and 64. Ideally the sample should be restricted to immigrants from both non-English-speaking and non-French speaking countries. However, the birthplace categories used in the Public Use Sample released from the 1991 Census of Canada do not permit identification of any French-speaking countries.<sup>4</sup> Aged males and females of all ages are excluded from the analysis at this stage to avoid the problems inherent in modeling labor-supply decisions.

According to the data in Table 1, about 5 percent of immigrants from non-English-speaking countries do not speak either English or French. Forty-seven percent of immigrants speak English and/or French but usually speak a non-official language at home. In other words, almost one-half of male immigrants from non-English-speaking countries in Canada have an incomplete shift towards the official languages of Canada. Forty-nine percent of male immigrants from non-English-speaking countries, however, speak English and/or French and usually speak one or both of these languages at home. The data in Table 1 are also presented separately for Québec and English Canada (other than for the Atlantic Provinces).<sup>5</sup> At this highly aggregated level of analysis, there is little difference between these two regions.

Table 2 reports the mean earnings of the three language categories for those who worked in Canada during 1990. There is a clear hierarchy in terms of earnings for the language categories. Immigrants who cannot conduct a conversation in an official language (L1) earn the least. Immigrants who can conduct a conversation in an official language but usually use a non-official

---

<sup>4</sup> While information on mother tongue could be used in place of country of origin, it would result in a non-random sample which, given the focus of the study, could result in considerable bias to the estimates.

<sup>5</sup> Only limited information is available on a number of key variables for individuals from the Atlantic provinces. Since less than one percent of the sample resides in the Atlantic provinces, estimations that

language at home (L2) occupy an intermediate position. Those who can conduct a conversation in an official language and usually use an official language at home (L3) earn the most. These differences are large and statistically significant.<sup>6</sup>

#### IV. Language Practice and Earnings

The relationship between language skills and earnings is generally assessed using a human capital earnings function.<sup>7</sup> This methodology is employed here. Specifically, the natural logarithm of annual earnings is assumed to be determined by the individual's educational attainment, labor market experience, weeks worked, province and region of residence, birthplace, duration in the destination, citizenship status and language proficiency. The language variables are based on those reported in Table 1. The possibility that the non-random nature of these language groups may result in biased estimates of the parameters of the wage function is taken in account using the generalization of Heckman's (1979) sample-selectivity correction proposed by Lee (1983). In this model, the *lambda* correction term computed for inclusion in the earnings function is constructed from estimates of a multinomial logit model of language practice. The specification of the language equation is developed in Chiswick and Miller (2000a).

Estimates of the earnings equation obtained when the data are pooled across language groups are listed in Table 3. These estimates, obtained using Ordinary Least Squares (OLS), show that much of the earnings differentials apparent in Table 2 are due to differences across the language groups in human capital endowments (other than language) and weeks worked. The first

---

exclude the Atlantic provinces will not be prone to significant sample selection bias problems.

<sup>6</sup> The percent differences between the earnings of the group who can conduct a conversation in an official language and usually speak an official language at home (L3) and the other two groups and associated 't' statistics are:

Language Group	Total Canada	English Canada	Québec
Can conduct a conversation in an official language but usually speaks a non-official language at home (L2)	-34.45 (21.87)	-32.95 (19.49)	-42.60 (10.05)
Cannot conduct a conversation in an official language (L1)	-69.98 (16.14)	-72.10 (15.40)	-57.89 (5.59)

<sup>7</sup> For studies of the effect of language on earnings among the native born or foreign born in Canada, see, for example, Meng (1987), Abbott and Beach (1987), Chiswick and Miller (1988, 1992), Shapiro and Stelcner (1997), and Pendakur and Pendakur (1999). For a recent study for the U.S., see Chiswick and Miller (2000 b).

three columns of Table 3 report the results for all of Canada, while columns (iv) and (v) report the results for English Canada and Québec, respectively.

The Table 3, column (i) results are for a conventional specification of the human capital earnings function that does not include the language variables. There are several notable features of these results. First, the increment in earnings associated with additional years of education for immigrants is 3.8 percent. This is lower than the 5.2 percent for the native born, but it is comparable to the 3.9 percent for the foreign born reported from analysis of the 1981 Census of Canada (see Chiswick and Miller 1988, 1992).

Second, the returns to labor market experience vary according to whether the experience was acquired pre- or post-migration. As duration of residence in Canada is a variable in the model, the returns to pre-migration experience are given by the coefficients on the experience variable,  $\partial LNEARN / \partial EXP = 0.018 - 0.0007(EXP)$ . Evaluated at  $EXP=10$  this equals 1.1 percent. The coefficients on the duration of residence variables record the differential returns to Canadian labor market experience over experience acquired abroad. This premium is  $\partial LNEARN / \partial PER = 0.036 - 0.00102(PER)$ . Evaluated at  $PER=10$ , this equals 2.6 percent. The sum of the coefficients on total experience and duration of residence give the earnings increase associated with being a year older and living an extra year in Canada, other variables the same. At  $EXP=PER=10$ , the partial effect on earnings of an extra year in Canada is 3.7 percent.

Third, citizenship is associated with 7 percent higher earnings. Citizenship was associated with a similar increment in earnings in the 1981 Census of Canada (see Chiswick and Miller 1992).

Fourth, the elasticity of earnings with respect to weeks worked is only 0.96. In other words, a one percent increase in weeks worked is associated with an increase in earnings of around 0.96 percent. A test of whether this coefficient is equal to unity gives a t-statistic of 1.76, which is statistically significant at about the 8 percent level. This elasticity measure is about five percentage points lower than the 1.01 reported in the study of the 1981 Census (see Chiswick and Miller (1992)).<sup>8</sup> Thus, in both years the elasticity is very close to unity.

---

<sup>8</sup> Note that Chiswick and Miller (1992) include immigrants from English-speaking countries in their sample. The comparison between 1981 and 1991 of the coefficients on the weeks worked variable is made on the basis

Fifth, there are considerable differences in the mean earnings, *ceteris paribus*, across the provinces. Compared with immigrants in Ontario, immigrants living in Québec have 23 percent lower earnings, those in the Prairies Provinces have 17 percent lower earnings, and immigrants resident in British Columbia have 10 percent lower earnings. In addition, residents of the major cities (Central Metropolitan Areas) have earnings about 11 percent higher than immigrants living outside of these areas.

The estimating equation is augmented by two language variables in Table 3, column (ii). The addition of these variables has only minor effects on the estimated impacts of the other variables. The results show that individuals who cannot conduct a conversation in an official language of Canada (L1) have a statistically significant 13 percent lower earnings ( $t = 2.96$ ) than the benchmark group of individuals who can speak an official language and usually speak an official language at home (L3). Individuals who can speak an official language but usually speak a non-official language at home (L3) have earnings 11 percent lower ( $t = 7.11$ ) than the benchmark group. There is no information in the Census of Canada on the degree of fluency among those who can speak an official language. The 11 percent earnings disadvantage could be capturing lesser official language fluency among those who continue to speak a non-official language at home. Or it could be capturing non-language influences that are related to the speaking of a non-official language at home (*e.g.*, ethnicity). To some extent the latter effect may be held constant through inclusion in the equation of country of birth variables.

Fourteen birthplace dummy variables are added to the model in Table 3, column (iii), with Italy as the benchmark. The majority of these are statistically significant, as a group they are highly significant, and a large number are associated with sizeable earnings differentials. The rank ordering of earnings by birthplace, *ceteris paribus*, from the lowest to the highest is: China, Middle East, Other Asia, Central and South America, Philippines, South Asia, Vietnam, Poland, Africa, Other Europe, (Italy, as the benchmark group), Portugal. Only immigrants from Germany, the USSR and Hong Kong are shown to have earnings that are not significantly different from the earnings of Italian immigrants.

---

of estimation of equations using the 1991 Census data that include immigrants from English-speaking countries.

The addition of the birthplace variables (which control for dimensions of ethnic origin) is associated with a slight reduction in the earnings disadvantage associated with the two language variables, but these language variables remain highly significant. Earnings in the two language groups are lower than for those who speak an official language at home by about 10 percent. This change in the specification is also associated with a reduction to around 1.9 percentage points in the premium to Canadian labor market experience over pre-immigration experience, when evaluated at 10 years in Canada.

Columns (iv) and (v) in Table 3 report results separately for English Canada and Québec. Only the model that includes the birthplace variables is considered. The results for English Canada in column (iv) are similar to those for all Canada (English Canada represents 83 percent of the total sample). In particular, the two language variables are associated with statistically significant 14 percent (L1) and 10 percent (L2) earnings disadvantages, respectively.

The findings for Québec are slightly different from those for English Canada. The returns to education are 1.5 percentage points higher in Québec (5.3 percent) than in English Canada (3.8 percent). The variable for whether the immigrant can speak an official language but usually speaks a non-official language at home is associated with a 14 percent earnings penalty. This effect is highly significant. The variable for immigrants who cannot conduct a conversation in an official language, however, is not statistically significant. The proportion of the sample in the latter group (2.7 percent) is less than in English Canada (4.1 percent), and the sample size is quite small. The differences in the language effects on earnings in English Canada and Québec may be a reflection of sample-selection bias. This issue is addressed next.

Table 4 presents results for earnings equations estimated for each of the three language states separately. Both OLS and selectivity-corrected estimates are presented. The data indicate selectivity bias only in the equation for individuals who can converse in an official language but who usually speak a non-official language at home. The *lambda* term has been constructed to be positive in each equation.<sup>9</sup> Hence the positive coefficient on *lambda* for language state L2 indicates positive selection into that state. Individuals who can converse in an official language but elect to use a non-official language at home have a higher mean

---

<sup>9</sup> The multinomial logit equations used to construct the lambda terms are reported in Appendix Table B-2.

earnings in that language state than would a random sample of immigrants. That is, this group of immigrants has a comparative advantage in this language state.<sup>10</sup>

There are a number of striking patterns in the other coefficients in Table 4. The increments in earnings associated with additional years of education are 5 percent among immigrants who can conduct a conversation in an official language and who usually use an official language at home (L3), and 3.3 percent (selectivity-corrected estimate) among immigrants who can conduct a conversation in an official language but who usually use a non-official language at home (L2), while earnings are not related to the level of education among the relatively small group of immigrants who cannot conduct a conversation in an official language (L1). This pattern suggests a complementarity between official language fluency and educational attainment among immigrants in the Canadian labor market.<sup>11</sup>

The pattern of the impact on earnings of pre-immigration experience for the three language groups is similar to that of educational attainment. The gains are greater for language group L3 than for either of the other two groups. Evaluated at EXP=10, the gains in earnings for an extra year of experience for language groups L3, L2 and L1 are, respectively, 2.0 percent, 0.9 percent, and a statistically insignificant 0.1 percent. As a form of human capital, experience acquired abroad can be more profitably transformed into higher earnings where the immigrant has shifted fully to the use of an official language in everyday life in Canada. Where an immigrant cannot conduct a conversation in an official language, pre-immigration experience, like educational attainment, is not associated with higher earnings.

In contrast, the premium to post-immigration experience is greater for immigrants with lesser fluency in an official language. Among immigrants who cannot conduct a conversation in an official language (L1) the increment in earnings with duration in Canada are around 2.3 percent, evaluated at 10 years of duration in Canada, but for the L2 group it is 2.1 percent and

---

<sup>10</sup> Estimates of the effect of language on earnings were also obtained using an IV approach. The minority language concentration and linguistic distance variables and their squared terms were used as identifying instruments. The coefficient in the earnings equation on L1 was  $-0.423$  ( $t = 0.53$ ) and that on L2 was  $-0.264$  ( $t = 2.31$ ). Estimated impacts obtained by IV that are around three times the OLS estimates are also found for other countries (see Dustman and van Soest 1997, Chiswick and Miller 1995).

<sup>11</sup> Schaafsma and Sweetman (1999) also find that the effect of schooling on earnings among immigrants in Canada is greater the greater is the Canadian-specific human capital, which in their study is measured by years of labor market experience in Canada, controlling for foreign experience and year of arrival in Canada, among other variables.

for the L3 group 1.2 percent. An extra year of experience in Canada does more for enhancing earnings among those with the poorest language skills. This suggests a substitution of one form of “post-immigration” human capital for another in the labor market. The earnings increments for pre-immigration experience can be added to the premiums for Canadian labor market experience to estimate the combined effects. The total returns to Canadian labor market experience, i.e. an extra year older in Canada, for each language group are found to be around 3 percent, in particular, 2.4 percent for L1, 3.0 percent for L2 and 3.2 percent for L3.

While there are other interesting findings in Table 4, only one further result will be discussed here, the coefficient on the log of weeks worked variable. This is much higher (1.01), and not significantly different from unity, for immigrants who usually speak an official language at home (L3) than for the other language groups. This suggests that the weekly rate of pay for immigrants in the L3 language category does not vary with the number of weeks worked. For the other two groups, however, the weekly rate of pay tends to decline with weeks worked; coefficient of 0.91 for L2 and 0.92 for L1. This would be expected where part-year work attracted a premium, such as employment in seasonally sensitive industries or occupations. This could be a consequence of greater seasonality in employment among those with less proficiency in the official languages.

Tables 5 and 6 repeat the analysis for adult male immigrants who completed their education prior to immigrating to Canada. These individuals are defined as those for whom age at immigration exceeds their number of years of schooling plus six years. If there is an ambiguity because of the interval nature of the period of arrival variable, the respondent was not included in the analysis. This procedure assumes that schooling was continuous without interruption from age 6 until it was completed.<sup>12</sup>

The basic patterns that emerge for this sample of men who completed their schooling prior to immigration (71 percent of the total) is somewhat different from what was found for all immigrants (Table 5). The effect of schooling on earnings is smaller in this group (3.4 percent compared to 4.2 percent when country of origin is held constant), but it is still highly significant. Pre-immigration labor market experience is no longer significant, except in English

---

<sup>12</sup> See Appendix Table B-3 for the means and standard deviations of the variables used in this analysis and Appendix Table B-4 for the multinomial logit model used to construct the *lambda* terms for inclusion in the

Canada. Duration of residence in Canada, on the other hand, has a larger effect (2.6 percent evaluated at  $PER = 10$  when country of birth is held constant in Table 5, column iii). The earnings differentials among the language groups are larger. Compared to those who use the official language at home (L3), the L2 speakers have 12 percent lower earnings and the L1 speakers have 14 percent lower earnings when country of birth is held constant.

When the analyses are performed separately by language group, as with the full sample, only the L2 speakers show sample selectivity (Table 6). The effect of schooling on earnings increases with proficiency: 4.6 percent for L3, 2.5 percent for L2 and the effect is small and not significant for L1. The effect of labor market experience prior to immigration is significant only for L2, and is 0.5 percent for L2 at  $EXP = 10$ . The effect of duration in Canada is significant for all three groups. Evaluated at  $PER = 10$ , the effects for the selectivity corrected analysis are 2.8 percent for L3, 2.3 percent for L2 and 2.6 percent for L1.

Thus, using a crude algorithm, among those who completed their schooling prior to immigrating to Canada, educational attainment and language skills appear to be complements, those with greater language skills have a larger effect of schooling on earnings. Pre-immigration labor market experience (i.e., total experience when duration is held constant) has no effect on earnings, except in English Canada. There is no systematic pattern for post-immigration experience with respect to language practice, although the effect is larger than in the full sample and highly significant (about 2.3 to 2.8 percent per year evaluated at  $PER = 10$ ).

## V. Summary and Conclusion

This study shows that language skills are a key determinant of earnings among immigrants in Canada. Immigrants who cannot conduct a conversation in an official language and those who, while being able to conduct a conversation in an official language, usually speak a non-official language at home, have earnings around 10 to 12 percent lower than immigrants who usually speak an official language at home, when other variables are the same. The earnings gap is larger, 12 to 14 percent, among those who completed their schooling prior to immigrating.

---

selectivity corrected estimates in Table 6.

There is evidence of selection into the group that can conduct a conversation in an official language but who usually speak a non-official language at home. The increment in earnings associated with an additional year of education is 5 percent among immigrants who usually speak an official language at home, around 3 percent for those who can conduct a conversation in an official language who usually speak a non-official language at home, and zero for immigrants who cannot conduct a conversation in an official language. When evaluated at 10 years, the impact of pre-immigration experience for these three groups is around 2 percent, 1 percent and zero, respectively, while the impact of duration of residence in Canada for the three groups is around 1 percent, 2 percent and 2.5 percent, respectively.

The analysis in this study is consistent with the hypothesis that greater proficiency in an official language enhances productivity in the Canadian labor market and enhances the effects on earnings of schooling and possibly pre-immigration labor market experience (complementarity in production), but that it can be a substitute in generating earnings for Canadian-specific labor market experience. Immigrants who lack proficiency in the official languages of Canada have lower earnings because of two effects: the direct effect of lower proficiency and an indirect effect through the smaller returns from schooling and pre-immigration experience.

The analysis of immigrant earnings presented in this paper has implications for immigration policy and absorption policy. An immigration policy that screens immigrants, in part, by their official language skills would result in higher earnings among the foreign born. An immigrant absorption policy that promotes investments in official language skills after migration and using these skills in the labor market and at home can enhance the value of the skills immigrants bring with them and hence the economic well-being of immigrants.

## APPENDIX A

### Definitions

*Definition of Population:* Foreign-born men from non-English-speaking countries, aged twenty-five to sixty-four who worked at least one week in 1990. Non-permanent residents (*i.e.*, persons on a student authorization, employment authorization, Minister's permit or a refugee claimant) are excluded from the analysis as the 1991 Census Public Use Microdata File (PUMF) does not contain information on the year of entry into Canada for this group. A small number of persons for whom data were not available on questions used in the construction of variables, and those resident in the Yukon and Northwest Territories, are also excluded from the analysis. Other sample exclusions are noted in the definitions. For further information on the data set, see Statistics Canada (1994).

*Earnings (LNEARN):* The natural logarithm of the sum of wage and salary income and self-employment income in 1990. Individuals reporting negative (self-employment loss) or zero earnings (voluntary work or "in kind" income) are assigned an earnings of \$100 (see Chiswick and Miller 1992). The PUMF truncates the income data at upper and lower limits for confidentiality reasons. These limits vary by region. In the construction of the earnings variable, values of 1.5 times these limits are used. Around one-third of one percent of wage and salary records and two percent of self-employment income records are in the open-end intervals.

*Language Practice (LANGTYPE):* LANGTYPE is a trichotomous variable. The first category (L1) comprises individuals who cannot conduct a conversation in English or French. The second category (L2) comprises individuals who can conduct a conversation in English or French, but usually speak a non-official language at home. The third category (L3) comprises those who can conduct a conversation in English or French and usually use an official language at home.

*Weeks Worked (LNWW):* The natural logarithm of the number of weeks worked by the respondent in 1990.

*Years of Education (EDUC):* This variable records the total years of full-time education. It is constructed from the Census information on total years of schooling for respondents who do not possess a university qualification. For individuals who possess a university qualification, the following years of full-time equivalent schooling are added to the years of secondary schooling: Diploma below bachelor level (2.4 years); Bachelor's degree (three years for those reporting three or fewer years of university, four years for all others); Diploma above bachelor level (four years for those reporting four or fewer years of university, five years for all others); Degree in medicine, dentistry, etc. (seven years); Master's Degree (six years); earned doctorate (eight years).

*Years Since Migration (YSM):* The census information on year at arrival is presented in single years for some arrival cohorts, small intervals for some cohorts in the non-Atlantic provinces,

and large intervals for the Atlantic provinces. A continuous measure was formed from this information by assigning midpoints to all arrival intervals, and subtracting this value from 1991. A quadratic specification is used. Individuals who arrived in Canada during 1991 are excluded from the study of earnings.

*Birthplace (BIRTH)*: The following countries or regions of birth are distinguished in the census file for immigrants resident outside the Atlantic provinces (listed in order of numerical importance): United Kingdom; Other Europe; Central and South America and Caribbean; Italy; United States; Southern Asia (*e.g.*, Bangladesh, India, Pakistan); Federal Republic of Germany; Africa; Poland; Middle East and Western Asia (*e.g.*, Turkey, Iran, Lebanon, Saudi Arabia); Portugal; Other Eastern and South East Asia (*e.g.*, Japan, South Korea, Singapore, Thailand); People's Republic of China; Hong Kong; Philippines; Vietnam; USSR; Other. For immigrants resident in the Atlantic Provinces, the only birthplace categories distinguished are: United States; United Kingdom; Other Europe; and Other. Immigrants from the United Kingdom, the United States and those from "Central America, Caribbean and Bermuda and South America" whose mother tongue is English are excluded from the analysis, given that study of language fluency is most appropriately focused on immigrants from non-English-speaking backgrounds. In addition, the small number of immigrants from the residual "Other" birthplace region are excluded from the analysis, as a direct line distance can not be assigned to this group in the construction of the "MILES" variable (see below). Immigrants from Italy are used as the benchmark group.

*Marital Status (MARRIED)*: This is a binary variable that is set equal to one for individuals who are married (includes common-law partners) and is defined to equal zero for all other marital states.

*Location*: Two location variables are used in the study. The first records province of residence. This information was grouped as follows: Atlantic Provinces (Newfoundland, Nova Scotia, New Brunswick, Prince Edward Island), Québec, Ontario, Prairies Provinces (Manitoba, Saskatchewan, Alberta), and British Columbia. The second locality variable records the size of the place of residence. Individuals residing in Census Metropolitan Areas (defined as having a population of at least 100,000 based on the 1986 Census) are distinguished from other individuals.

*Citizenship (CITIZEN)*: Individuals who hold Canadian citizenship are distinguished from immigrants who have not yet become citizens.

*Minority Language Concentration (CONC)*; *Linguistic Distance (LD)*; *Refugee (REFUGEE)*; *Colony (COLONY)*; *Direct-Line Distances (MILES)*; for information on these instruments, see Chiswick and Miller (2000a).
